

Moslik

Automated verification system for accountants

Upload a bank statement and an e-invoice register. The system compares the numbers for every counterparty and shows exactly where they disagree.

moslik.uz

Tashkent, Uzbekistan

President Tech Awards 2026

Every month, the same two files — compared by eye

For each client company an accountant in Uzbekistan reconciles two independent records: money that actually moved through the **bank account**, and invoices issued or received in the state **e-invoice system** — mandatory since 2020.

01

One company, many names

The same counterparty is written differently by every bank. In our reference data a single tax ID appeared under **four different names** in one statement.

02

Noise hides the signal

Utility, treasury and bank-fee lines flood the table. In one 7-month dataset **13 of 48 counterparties** were not trading partners at all.

03

Every bank exports differently

Six sample files from real banks contained **four distinct layouts** — including HTML disguised as .xls and CSV in two encodings.

The error does not stay inside the company

50 278 000

UZS of invoices with **no matching payment** — found by the system in real data, missed by the accountant who had already closed the period.

1 366 176

UZS · second unmatched balance

227 503

UZS · third unmatched balance

Where it ends up

Bank records and e-invoice records feed the same VAT return. When they disagree, the difference is not an internal inconvenience — it becomes a reporting discrepancy in front of the tax authority.

The work is slow, repetitive and done under deadline. That is exactly the kind of work software should be doing.

Two files in. Every difference out.

Moslik reads both files **as they are** — no reformatting, no template, no manual column mapping — and produces a counterparty-level comparison.

Matched by tax ID	not by company name
Money paid	vs invoices received
Money received	vs invoices issued
Difference sign	positive = they owe you

The system never adjusts a number to make a total balance. It reports what the files say — the correction stays the accountant's decision.

moslik.uz · reconciliation

COUNTERPARTY	PAID	INVOICED	DIFF.
YOSH ULGURJI	473 954 000	473 954 000	0
ANGREN ADMIRAL	8 271 000	8 271 000	0
HUDUDGAZ	0	50 278 000	-50 278 000

Of 3 counterparties, 1 has a difference — 50 278 000 UZS.

Three steps, a few seconds

1

Upload

The bank statement and the invoice register, in whatever format the bank produced — .xls, .xlsx, CSV, or HTML renamed to .xls.

2

Confirm what was read

The system states what it recognised — which bank layout, which account, which period — and verifies the file against itself before comparing anything.

3

Read the differences

Counterparties with a gap are separated out, with the amount and the direction. Exportable as a five-sheet Excel report or an official reconciliation act.

Work that takes **several days per client, every month** is finished while the accountant is still looking at the screen.

Not a viewer. An audit tool.

The balance equation

Opening balance + credit – debit must equal the closing balance. If a bank export has debit and credit swapped, the file's own total **still adds up** — this check does not.

Category protection

Utility and treasury lines are set aside but **never deleted** — the grand total always stays complete. The system refuses to classify a counterparty on its own; it warns instead.

Shared format memory

An unfamiliar bank layout is learned once and recognised afterwards. The memory is shared, so **every new user strengthens the system** for everyone else.

The design rule behind all three: the two kinds of mistake do not cost the same. Showing one extra row is visible and harmless. Hiding one real row makes money disappear silently — so the system is built never to do the second.

A total that adds up can still be wrong

Swap the debit and credit columns of a statement and every subtotal in the file remains correct. Nothing looks wrong. The balance equation catches it on the first row.

Correct file

$1\,000\,000 + 300\,000 - 200\,000$
= **1 100 000** ✓

Same file, columns swapped

$1\,000\,000 + 200\,000 - 300\,000$
= **900 000** X — flagged

Verified to the tiyin on real statements

BANK FILE	CLOSING BALANCE	CHECK
ULUGBEK	1 923 908.59	✓
STROY MARKET	9 619 037.41	✓
ANGREN ADMIRAL	1 646 801.32	✓
KARVON	8 755 600.68	✓
IMANMAX	25 774 688.88	✓

A deliberately corrupted file is part of the automated test suite — it proves that the file's own totals cannot detect the swap, and that this check can.

Measured, not claimed

6

real bank export files, four distinct layouts

58

automated checks, re-run on every change

1.37bn

UZS of turnover reconciled in testing

35

counterparties, 152 transfers, 159 invoices

Built against reality, not a spec

Every rule came from a real file that broke an earlier assumption — debit and credit on separate sheets, a payment description containing the word "balance", a date parsed as an amount. Each one is now a permanent regression test.

Already live in four languages

Uzbek (Latin), Uzbek (Cyrillic), Russian and English — each on its own address, so the product is usable by an accountant in the language they actually work in.

The documents are already digital. Nobody checks that they agree.

LAYER	WHO SERVES IT
Invoices	Didox — 250 000+ companies; Faktura.uz
Banking	Dibank — 25+ Uzbek banks connected
Verification	open — no independent tool

E-invoicing has been mandatory for all legal entities and individual entrepreneurs since **2020**, and was extended to the **self-employed in 2026** — sharply increasing the number of people who must keep formal records.

Positioning

They move documents.

We check them.

Primary customer: the accountant or accounting bureau serving many client companies. Outsourced accounting packages in Uzbekistan typically start around 1 000 000 UZS per client per month — the hours Moslik removes are billable hours today.

Priced per workspace, never per reconciliation

Why the limit is on companies, not reconciliations. An accountant does not reconcile once — they upload, see a gap, fix the source file and upload again. Counting reconciliations would charge the user for the product working properly.

Where the price came from. The first figure was an estimate. It was replaced after asking a practising accountant what they would actually pay. At this stage volume is worth more than revenue: every new user brings a new bank format into the shared memory.

Built and verified. Now it needs users.

DONE

Working product

Both reconciliation directions, official reconciliation act, receivables ageing, five-sheet Excel export, isolated workspaces, four languages.

NOW

Closed pilot, 10 accountants

Success is measured by how many return in the **second month** — not by feature count. No new features until that number exists.

NEXT

Straight to the source

Pull invoices through the e-invoice operator API, then bank data directly (1C Client-Bank, MT940, ISO 20022 camt.053) — removing the file upload entirely.

Stated plainly: the product is pre-launch. It has been validated against real company data, not against paying users — and the next milestone is designed to change exactly that.

Three people, one product

Diyorbek Abdulhamidov

Founder & CEO

Built the reconciliation engine and the bank-format parsers. Owns product and engineering.

Og'abek Husanov

Web Developer

Interface and reporting screens.
Cyber University of Uzbekistan.

Shahzodbek Turabiddinov

Data Engineer

File formats and data validation.
